

## PTFE vs. PFOA

### PTFE vs PFOA

The definition of PFAS includes an estimated 14,000 molecules and compounds that significantly vary in their physiochemical properties and should not be regulated in the same manner. For example, PTFE and PFOA have different chemical structures and properties (see chart below). PTFE is a stable, inert, non-polar polymer mainly used for its chemical resistance and non-stick properties, while PFOA is a bioaccumulative, amphiphilic surfactant with environmental mobility concerns and has been phased-out due to its potential health risks.

Below are a few examples of the broad agreement on this scientific fact:

- Department of Defense [report](#) states “A variety of broad molecular structure descriptors, without regard to the individual substance’s toxicity profile and hazard characterization, are used to define the chemical class “PFAS.” These structural definitions do not inform whether a substance is harmful but only communicate that the substances share common structural traits to varying degrees.”
- EPA’s [National PFAS Testing Strategy](#) states “Most of the hundreds of PFAS currently in commerce have limited or no toxicity data.”
- Organisation for Economic Co-operation and Development (OECD) issued a [report](#) stating, “As PFASs are a chemical class with diverse molecular structures and physical, chemical and biological properties, it is highly recommended that such diversity be properly recognized and communicated in a clear, specific and descriptive manner. The term “PFASs” is a broad, general, non-specific term, which does not inform whether a compound is harmful or not, but only communicates that the compounds under this term share the same trait for having a fully fluorinated methyl or methylene carbon moiety.”
- Canada PFAS risk [management](#) approach excludes fluoropolymers.

Property	PTFE	PFOA
Chemical Structure	<p>Linear polymer composed of repeating (can be thousands) tetrafluoroethylene monomers - <math>(CF_2-CF_2)_n</math></p>  <p>The diagram shows a horizontal chain of eight carbon atoms (C) connected by single bonds. Each carbon atom is bonded to two fluorine atoms (F), one above and one below. Dashed lines extend from the first and last carbon atoms, indicating the polymer chain continues.</p>	<p>8-carbon chain fully fluorinated except for the last carbon which is attached to a carboxylic acid group - <math>C_8HF_{15}O_2</math></p>  <p>The diagram shows a chain of eight carbon atoms. The first seven carbons are each bonded to two fluorine atoms. The eighth carbon is part of a carboxylic acid group, bonded to two oxygen atoms (one double-bonded, one single-bonded to a hydrogen atom).</p>
Water Solubility	Insoluble	Soluble
Mobility in Environment	Stable and does not dissolve or migrate easily in the environment due to its solid form and chemical inertness	Can move through soil and water due to its solubility and persistence in the environment
Bioaccumulation	Not bioaccumulative; it is inert and does not absorb into living tissues	Highly bioaccumulative; it tends to persist in biological systems, accumulating over time and potentially causing health issues
Polarity	Non-polar	PFOA is considered amphiphilic because it has both hydrophobic (non-polar) and hydrophilic (polar) parts
Toxicity	Inert and non-toxic; does not react with other chemicals easily and poses minimal risk under normal conditions	Toxic
